After that, the frameworks were veneered with porcelain and the biscuit bake was tried, in the patient's mouth. The crowns were then completed and fitted (Fig 19). An opaque white composite cement was used for the crown on tooth 11 in order to prevent the dark colour of the abutment from showing through.

Treatment outcome and conclusion
On follow-up two months after insertion, the esthetics were satisfactory and the two crowns harmonized well with the rest of the dentition (Fig 20). The soft tissue in region 21 was similar to the rest of the gingiva in color and texture, and the papillae mesial and distal to 21 were almost completely filled up. In the final radiograph the marginal bone level seemed ideal (Fig 21). The patient appeared highly satisfied with the restoration.
